

Multi category chi-squared tests: Takeaways

by Dataquest Labs, Inc. - All rights reserved © 2019

Syntax

- Calculating the chi-squared value:

```
observed = [6662, 1179, 15128, 9592]
expected = [5249.8, 2597.4, 16533.5, 8180.3]
values = []

for i, obs in enumerate(observed):
    exp = expected[i]
    value = (obs - exp) ** 2 / exp
    values.append(value)

chisq_gender_income = sum(values)
```

- Finding the chi-squared value and p-value using `scipy.stats.chisquare`:

```
import numpy as np

from scipy.stats import chisquare

observed = np.array([6662, 1179, 15128, 9592])
expected = np.array([5249.8, 2597.4, 16533.5, 8180.3])

chisq_value, pvalue_gender_income = chisquare(observed, expected)
```

- Using the `pandas.crosstab` function to print a table that shows frequency counts:

```
import pandas

table = pandas.crosstab(income["sex"], [income["high_income"]])

print(table)
```

- Using the `scipy.stats.chi2_contingency` function to generate the expected values:

```
import numpy as np

from scipy.stats import chi2_contingency

observed = np.array([[5, 5], [10, 10]])

chisq_value, pvalue, df, expected = chi2_contingency(observed)
```

Concepts

- In a multiple category chi-squared test, we calculate expected values across our whole dataset.
 - We can calculate the chi-squared value by using the following steps:
 - Subtract the expected value from the observed value.
 - Subtract the difference.
 - Divide the squared difference by the expected value.
 - Repeat for all observed and expected values and add up all the values.
 - Formula for chi-squared:
-
- Finding that a result isn't significant doesn't mean that no association between the columns exists. Finding a statistically significant result doesn't imply anything about what the correlation is.
 - Chi-squared tests can only be applied in the case where each possibility within a category is independent.
